

# Package ‘basicspace’

December 3, 2024

**Type** Package

**Title** Recovering a Basic Space from Issue Scales

**Version** 0.25

**Date** 2024-12-02

**Author** Royce Carroll [aut],  
Christopher Hare [aut, cre],  
Jeffrey B. Lewis [aut],  
James Lo [aut],  
Keith T. Poole [aut],  
Howard Rosenthal [aut]

**Maintainer** Christopher Hare <cdhare@ucdavis.edu>

**Description** Provides functions to estimate latent dimensions of choice and judgment using Aldrich-McKelvey and Blackbox scaling methods, as described in Poole et al. (2016, <doi:10.18637/jss.v069.i07>). These techniques allow researchers (particularly those analyzing political attitudes, public opinion, and legislative behavior) to recover spatial estimates of political actors' ideal points and stimuli from issue scale data, accounting for perceptual bias, multidimensional spaces, and missing data. The package uses singular value decomposition and alternating least squares (ALS) procedures to scale self-placement and perceptual data into a common latent space for the analysis of ideological or evaluative dimensions. Functionality also include tools for assessing model fit, handling complex survey data structures, and reproducing simulated datasets for methodological validation.

**License** GPL-2

**Depends** R (>= 3.0.0), tools

aldmck	<i>Aldrich-McKelvey Scaling</i>
--------	---------------------------------

---

### Description

aldmck is a function that takes a matrix of perceptual data, such as liberal-conservative rankings of various stimuli, and recovers the true location of those stimuli in a spatial model. It differs from procedures such as wnominate, which instead use preference data to estimate candidate and citizen positions. The procedure here, developed by John Aldrich and Richard McKelvey in 1977, is restricted to estimating data with no missing values and only in one dimension. Please refer to the blackbox and blackbox\_transpose functions in this package for procedures that accomodate missing data and multidimensionality estimates.

### Usage

```
aldmck(data, respondent=0, missing=NULL, polarity, verbose=FALSE)
```

**Arguments**

data	matrix of numeric values, containing the perceptual data. Respondents should be organized on rows, and stimuli on columns. It is helpful, though not necessary, to include row names and column names.
respondent	integer, specifies the column in the data matrix of the stimuli that contains the respondent's self-placement on the scale. Setting respondent = 0 specifies that the self-placement data is not available. Self-placement data is not required to estimate the locations of the stimuli, but is required if recovery of the respondent ideal points, or distortion parameters is desired. Note that no distortion parameters are estimated in AM without self-placements because they are not needed, see equation (24) in Aldrich and McKelvey (1977) for proof.
missing	vector or matrix of numeric values, sets the missing values for the data. NA values are always treated as missing regardless of what is set here. Observations with missing data are discarded before analysis. If input is a vector, then the vector is assumed to contain the missing value codes for all the data. If the input is a matrix, it must be of dimension $p \times q$ , where $p$ is the maximum number of missing values and $q$ is the number of columns in the data. Each column of the inputted matrix then specifies the missing data values for the respective variables in data. If null (default), no missing values are in the data other than the standard NA value.
polarity	integer, specifies the column in the data matrix of the stimuli that is to be set on the left side (generally this means a liberal)
verbose	logical, indicates whether aldmck should print out detailed output when scaling the data.

**Value**

An object of class aldmck.

legislators	vector, containing the recovered locations of the stimuli. The names of the stimuli are attached if provided as column names in the argument data, otherwise they are generated sequentially as 'stim1', 'stim2', etc.
respondents	matrix, containing the information estimated for each respondent. Observations which were discarded in the estimation for missing data purposes have been NA'd out: intercept Intercept of perceptual distortion for respondent. weight Weight of perceptual distortion for respondent. idealpt Estimated location of the respondent. Note that these positions are still calculated for individuals with negative weights, so these may need to be discarded. Note that this will not be calculated if self-placements are not provided in the data. selfplace The self-reported location of the individual, copied from the data argument if respondent is not set to 0. polinfo Estimated political information of respondent, calculated as the correlation between the true and reported stimulus locations. The validation

of this measure is provided in the article by Palfrey and Poole in the references. Note that this measure is included even for respondents that were not used in the estimation. Individuals with negative weights have also been assigned a political information score of 0, rather than negative scores.

eigenvalues	A vector of the eigenvalues from the estimation.
AMfit	Ratio of overall variance to perceptions in scaled data divided by average variance. This measure of fit, described by Aldrich and McKelvey, measures the amount of reduction of the variance of the scaled over unscaled data.
N	Number of respondents used in the estimation (i.e. had no missing data)
N.neg	Number of cases with negative weights. Only calculated if respondent self-placements are specified, will equal 0 if not.
N.pos	Number of cases with positive weights. Only calculated if respondent self-placements are specified, will equal 0 if not.

---

blackbox

*Blackbox Scaling*

---

## Description

blackbox is a function that takes a matrix of survey data in which individuals place themselves on continuous scales across multiple issues, and locates those citizens in a spatial model of voting. Mathematically, this function generalizes the singular value of a matrix to cases in which there is missing data in the matrix. Scales generated using perceptual data (i.e. scales of legislator locations using liberal-conservative rankings by survey respondents) should instead use the blackbox\_transpose function in this package instead.

## Usage

```
blackbox(data, missing=NULL, verbose=FALSE, dims=1, minscale)
```

## Arguments

data	matrix of numeric values containing the issue scale data. Respondents should be organized on rows, and stimuli on columns. It is helpful, though not necessary, to include row names and column names.
missing	vector or matrix of numeric values, sets the missing values for the data. NA values are always treated as missing regardless of what is set here. Observations with missing data are discarded before analysis. If input is a vector, then the vector is assumed to contain the missing value codes for all the data. If the input is a matrix, it must be of dimension $p \times q$ , where $p$ is the maximum number of missing values and $q$ is the number of columns in the data. Each column of the inputted matrix then specifies the missing data values for the respective variables in data. If null (default), no missing values are in the data other than the standard NA value.
verbose	logical, indicates whether aldmck should print out detailed output when scaling the data.
dims	integer, specifies the number of dimensions to be estimated.
minscale	integer, specifies the minimum number of responses a respondent needs to provide to be used in the scaling.

**Value**

An object of class `blackbox`.

<code>stimuli</code>	vector of data frames of length <code>dims</code> . Each data frame presents results for estimates from that dimension (i.e. <code>x\$stimuli[[2]]</code> presents results for dimension 2). Each row contains data on a separate stimulus, and each data frame includes the following variables: <code>N</code> Number of respondents who provided a response to this stimulus. <code>c</code> Stimulus intercept. <code>w1</code> Estimate of the stimulus weight on the first dimension. If viewing the results for a higher dimension, higher dimension results will appear as <code>w2</code> , <code>w3</code> , etc. <code>R2</code> The percent variance explained for the stimulus. This increases as more dimensions are estimated.
<code>individuals</code>	vector of data frames of length <code>dims</code> . Each data frame presents results for estimates from that dimension (i.e. <code>x\$stimuli[[2]]</code> presents results for dimension 2). Individuals that are discarded from analysis due to the <code>minscale</code> constraint are NA'd out. Each row contains data on a separate stimulus, and each data frame includes the following variables: <code>c1</code> Estimate of the individual intercept on the first dimension. If viewing the results for a higher dimension, higher dimension results will appear as <code>c2</code> , <code>c3</code> , etc.
<code>fits</code>	A data frame of fit results, with elements listed as follows: <code>SSE</code> Sum of squared errors. <code>SSE.explained</code> Explained sum of squared error. <code>percent</code> Percentage of total variance explained. <code>SE</code> Standard error of the estimate, with formula provided on pg. 973 of the article cited below. <code>singular</code> Singular value for the dimension.
<code>Nrow</code>	Number of rows/stimuli.
<code>Ncol</code>	Number of columns used in estimation. This may differ from the data set due to columns discarded due to the <code>minscale</code> constraint.
<code>Ndata</code>	Total number of data entries.
<code>Nmiss</code>	Number of missing entries.
<code>SS_mean</code>	Sum of squares grand mean.
<code>dims</code>	Number of dimensions estimated.

blackbox\_transpose      *Blackbox transpose Scaling*

---

## Description

blackbox\_transpose is a function that takes a matrix of perceptual data, such as liberal-conservative rankings of various stimuli, and recovers the true location of those stimuli in a spatial model. It differs from procedures such as wnominate, which instead use preference data to estimate candidate and citizen positions. The procedure here generalizes the technique developed by John Aldrich and Richard McKelvey in 1977, which is also included in this package as the aldmck function.

## Usage

```
blackbox_transpose(data, missing=NULL, verbose=FALSE, dims=1, minscale)
```

**Arguments**

<code>data</code>	matrix of numeric values, containing the perceptual data. Respondents should be organized on rows, and stimuli on columns. It is helpful, though not necessary, to include row names and column names.
<code>missing</code>	vector or matrix of numeric values, sets the missing values for the data. NA values are always treated as missing regardless of what is set here. Observations with missing data are discarded before analysis. If input is a vector, then the vector is assumed to contain the missing value codes for all the data. If the input is a matrix, it must be of dimension $p \times q$ , where $p$ is the maximum number of missing values and $q$ is the number of columns in the data. Each column of the inputted matrix then specifies the missing data values for the respective variables in data. If null (default), no missing values are in the data other than the standard NA value.
<code>verbose</code>	logical, indicates whether <code>aldmck</code> should print out detailed output when scaling the data.
<code>dims</code>	integer, specifies the number of dimensions to be estimated.
<code>minscale</code>	integer, specifies the minimum number of responses a respondent needs to provide to be used in the scaling.

**Value**

An object of class `blackbt`.

<code>stimuli</code>	<p>vector of data frames of length <code>dims</code>. Each data frame presents results for estimates from that dimension (i.e. <code>x\$stimuli[[2]]</code> presents results for dimension 2). Each row contains data on a separate stimulus, and each data frame includes the following variables:</p> <ul style="list-style-type: none"> <li><code>N</code> Number of respondents who ranked this stimulus.</li> <li><code>coord1D</code> Location of the stimulus in the first dimension. If viewing the results for a higher dimension, higher dimension results will appear as <code>coord2D</code>, <code>coord3D</code>, etc.</li> <li><code>R2</code> The percent variance explained for the stimulus. This increases as more dimensions are estimated.</li> </ul>
<code>individuals</code>	<p>vector of data frames of length <code>dims</code>. Each data frame presents results for estimates from that dimension (i.e. <code>x\$stimuli[[2]]</code> presents results for dimension 2). Individuals that are discarded from analysis due to the <code>minscale</code> constraint are NA'd out. Each row contains data on a separate stimulus, and each data frame includes the following variables:</p> <ul style="list-style-type: none"> <li><code>c</code> Estimate of the individual intercept.</li> <li><code>w1</code> Estimate of the individual slope. If viewing the results for a higher dimension, higher dimension results will appear as <code>w2</code>, <code>w3</code>, etc.</li> <li><code>R2</code> The percent variance explained for the respondent. This increases as more dimensions are estimated.</li> </ul>
<code>fits</code>	A data frame of fit results, with elements listed as follows:
<code>SSE</code>	Sum of squared errors.

SSE.explained Explained sum of squared error.  
 percent Percentage of total variance explained.  
 SE Standard error of the estimate, with formula provided in the article cited below.  
 singular Singular value for the dimension.

Nrow Number of rows/stimuli.  
 Ncol Number of columns used in estimation. This may differ from the data set due to columns discarded due to the minscale constraint.  
 Ndata Total number of data entries.  
 Nmiss Number of missing entries.  
 SS\_mean Sum of squares grand mean.  
 dims Number of dimensions estimated.

boot\_aldmck

*Bootstrap of Aldrich-McKelvey Scaling*

---

**Description**

boot\_aldmck is a function automates the non-parametric bootstrapping of aldmck. The original function takes a matrix of perceptual data, such as liberal-conservative rankings of various stimuli, and recovers the true location of those stimuli in a spatial model. The bootstrap simply applies this estimator across multiple resampled data sets and stores the results of each iteration in a matrix. These results can be used to estimate uncertainty for various parameters of interest, and can be plotted using the plot.boot\_aldmck function.

**Usage**

```
boot_aldmck(data, respondent = 0, missing=NULL, polarity, iter=100)
```

**Arguments**

data	matrix of numeric values, containing the perceptual data. Respondents should be organized on rows, and stimuli on columns. It is helpful, though not necessary, to include row names and column names.
respondent	integer, specifies the column in the data matrix of the stimuli that contains the respondent's self-placement on the scale. Setting respondent = 0 specifies that the self-placement data is not available. Self-placement data is not required to estimate the locations of the stimuli, but is required if recovery of the respondent ideal points, or distortion parameters is desired. Note that no distortion parameters are estimated in AM without self-placements because they are not needed, see equation (24) in Aldrich and McKelvey (1977) for proof.
missing	vector or matrix of numeric values, sets the missing values for the data. NA values are always treated as missing regardless of what is set here. Observations with missing data are discarded before analysis. If input is a vector, then the vector is assumed to contain the missing value codes for all the data. If the input is a matrix, it must be of dimension $p \times q$ , where $p$ is the maximum number of missing values and $q$ is the number of columns in the data. Each column

	of the inputted matrix then specifies the missing data values for the respective variables in data. If null (default), no missing values are in the data other than the standard NA value.
polarity	integer, specifies the column in the data matrix of the stimuli that is to be set on the left side (generally this means a liberal)
iter	integer, is the number of iterations the bootstrap should run for.

**Value**

An object of class boot\_aldmck. This is simply a matrix of dimensions iter x number of stimuli. Each row stores the estimated stimuli locations for each iteration.

boot\_blackbt

*Bootstrap of Blackbox Transpose Scaling*

---

## Description

boot\_blackbt is a function automates the non-parametric bootstrapping of blackbox\_transpose. The original function takes a matrix of perceptual data, such as liberal-conservative rankings of various stimuli, and recovers the true location of those stimuli in a spatial model. The bootstrap simply applies this estimator across multiple resampled data sets and stores the results of each iteration in a matrix. These results can be used to estimate uncertainty for various parameters of interest, and can be plotted using the plot.boot\_blackbt function.

## Usage

```
boot_blackbt(data, missing=NULL, dims=1, dim.extract=dims, minscale,
             iter=100, verbose=FALSE)
```

## Arguments

data	matrix of numeric values, containing the perceptual data. Respondents should be organized on rows, and stimuli on columns. It is helpful, though not necessary, to include row names and column names.
missing	vector or matrix of numeric values, sets the missing values for the data. NA values are always treated as missing regardless of what is set here. Observations with missing data are discarded before analysis. If input is a vector, then the vector is assumed to contain the missing value codes for all the data. If the input is a matrix, it must be of dimension p x q, where p is the maximum number of missing values and q is the number of columns in the data. Each column of the inputted matrix then specifies the missing data values for the respective variables in data. If null (default), no missing values are in the data other than the standard NA value.
dims	integer, specifies the number of dimensions to be estimated.
dim.extract	integer, specifies which dimension to extract results for the bootstrap from.
minscale	integer, specifies the minimum number of responses a respondent needs to provide to be used in the scaling.
iter	integer, number of iterations the bootstrap should run for.
verbose	logical, indicates whether the progress of blackbox_transpose (at each 10th iteration) should be printed to the screen.

## Value

An object of class boot\_blackbt. This is simply a matrix of dimensions iter x number of stimuli. Each row stores the estimated stimuli locations for each iteration.

 colombia

---

 2004 PELA Liberal-Conservative Scales.
 

---

**Description**

Liberal-Conservative 10-point scales from the University of Salamanca’s Parliamentary Elites of Latin America (PELA) survey. Stored as a matrix of integers. The number 99 is a missing value. These data come from Sebastian Saiegh and are used in the paper and book cited below.

**Usage**

```
data(colombia)
```

**Value**

The data is formatted as an integer matrix with the following elements.

colombia	matrix, containing reported placements of various stimuli on a 10 point Liberal-Conservative scale:
id	Respondent ID.
party	Respondent party.
departam	Respondent district.
entrey	Interviewer ID.
p1_uribista	Placement of “Partido Liberal Uribista” on 10 point scale.
p1_oficial	Placement of “Partido Liberal Oficial” on 10 point scale.
conservator	Placement of “Partido Conservador” on 10 point scale.
polo	Placement of “Polo” on 10 point scale.
union_cristiana	Placement of “Union Cristiana” on 10 point scale.
salvation	Placement of “Salvacion” on 10 point scale.
urine	Placement of Mr. Uribe on 10 point scale.
antanas	Placement of Mr. Antanas on 10 point scale.
gomez	Placement of Mr. Gomez on 10 point scale.
garzon	Placement of Garzon on 10 point scale.
holgin	Placement of Holguin on 10 point scale.
rivera	Placement of Rivera on 10 point scale.
self	Respondent self placement on 10 point scale.

---

fit

*Extraction function for fit of scaling model*

---

## Description

fit is a convenience function to extract the model fit statistics from an aldmck, blackbox, or blackbt object.

## Usage

```
fit(object)
```

## Arguments

object            an aldmck, blackbox, or blackbt output object.

**Value**

The model fit statistics of the estimated output, which can also be recovered as `object$fits` (for `blackbox` or `blackbt` objects) or `object$AMfit` (for `aldmck` objects). Please refer to the documentation of `aldmck`, `blackbox`, or `blackbox_transpose` for specifics.

Issues1980

*1980 Issues Scales*

---

**Description**

Issue scales from the 1980 National Election Study. The numbers 0, 8, and 9 are considered to be missing values, except for the two abortion scales, where '7' is also a missing value. Hence, it must be recoded as in the example shown below before scaling. The data is used as an example for `blackbox()`.

**Usage**

```
data(LC1980)
```

**Value**

The data is formatted as an numeric matrix with the following elements.

Issues	matrix, containing reported self-placements along various stimuli on a 7 point Liberal-Conservative scales (with the exception of abortion scales, which are 4 point):
libcon1	Liberal-conservative self-placement on 7 point scale.
defense	Defense spending self-placement on 7 point scale.
govserv	Government service on 7 point scale.
inflation	Importance of inflation self-placement on 7 point scale.
abortion1	Attitude on abortion 4 point scale.
taxcut	Support for tax cut on 7 point scale.
libcon2	Liberal-conservative self-placement on 7 point scale.

govhelpmin Government aid on 7 point scale.  
 russia Attitude towards Russia on 7 point scale.  
 womenrole Role of women on 7 point scale.  
 govjobs Placement of Democrats on 7 point scale.  
 equalrights Support for equal rights on 7 point scale.  
 busing Opinion on busing on 7 point scale.  
 abortion2 Another attitude on abortion on 4 point scale.

*Blackbox Estimate, 1980 ANES Issue Scales.*

---

### Description

Blackbox estimates from issues scales from the 1980 American National Election Study.

### Usage

```
data(Issues1980_bb)
```

### Value

An object of class `blackbox`.

<code>stimuli</code>	vector of data frames of length <code>dims</code> . Each data frame presents results for estimates from that dimension (i.e. <code>x\$stimuli[[2]]</code> presents results for dimension 2). Each row contains data on a separate stimulus, and each data frame includes the following variables: <code>N</code> Number of respondents who provided a response to this stimulus. <code>c</code> Stimulus intercept. <code>w1</code> Estimate of the stimulus weight on the first dimension. If viewing the results for a higher dimension, higher dimension results will appear as <code>w2</code> , <code>w3</code> , etc. <code>R2</code> The percent variance explained for the stimulus. This increases as more dimensions are estimated.
<code>individuals</code>	vector of data frames of length <code>dims</code> . Each data frame presents results for estimates from that dimension (i.e. <code>x\$stimuli[[2]]</code> presents results for dimension 2). Individuals that are discarded from analysis due to the <code>minscale</code> constraint are NA'd out. Each row contains data on a separate stimulus, and each data frame includes the following variables: <code>c1</code> Estimate of the individual intercept on the first dimension. If viewing the results for a higher dimension, higher dimension results will appear as <code>c2</code> , <code>c3</code> , etc.
<code>fits</code>	A data frame of fit results, with elements listed as follows: <code>SSE</code> Sum of squared errors. <code>SSE.explained</code> Explained sum of squared error. <code>percent</code> Percentage of total variance explained. <code>SE</code> Standard error of the estimate, with formula provided on pg. 973 of the article cited below. <code>singular</code> Singular value for the dimension.

Nrow	Number of rows/stimuli.
Ncol	Number of columns used in estimation. This may differ from the data set due to columns discarded due to the minscale constraint.
Ndata	Total number of data entries.
Nmiss	Number of missing entries.
SS_mean	Sum of squares grand mean.
dims	Number of dimensions estimated.

 LC1980

---

*1980 Liberal-Conservative Scales.*

---

### Description

Liberal-Conservative 7-point scales from the 1980 National Election Study. Includes (in order) self-placement, and rankings of Carter, Reagan, Kennedy, Anderson, Republican party, Democratic Party. Stored as a matrix of integers. The numbers 0, 8, and 9 are considered to be missing values.

### Usage

```
data(LC1980)
```

### Value

The data is formatted as an integer matrix with the following elements.

LC1980	matrix, containing reported placements of various stimuli on a 7 point Liberal-Conservative scale:
	Self Self-placement on 7 point scale.
	Carter Placement of Carter on 7 point scale.
	Reagan Placement of Reagan on 7 point scale.
	Kennedy Placement of Kennedy on 7 point scale.
	Anderson Placement of Anderson on 7 point scale.
	Republicans Placement of Republicans on 7 point scale.
	Democrats Placement of Democrats on 7 point scale.

*Blackbox Transpose Estimate, 1980 Liberal-Conservative Scales.*

---

## Description

Blackbox-Transpose estimates from Liberal-Conservative 7-point scales from the 1980 National Election Study. Estimates in 3 dimensions.

## Usage

```
data(LC1980_bbt)
```

## Value

An object of class blackbt.

`stimuli` vector of data frames of length `dims`. Each data frame presents results for estimates from that dimension (i.e. `x$stimuli[[2]]` presents results for dimension 2). Each row contains data on a separate stimulus, and each data frame includes the following variables:

	N	Number of respondents who ranked this stimulus.
	coord1D	Location of the stimulus in the first dimension. If viewing the results for a higher dimension, higher dimension results will appear as coord2D, coord3D, etc.
	R2	The percent variance explained for the stimulus. This increases as more dimensions are estimated.
individuals		vector of data frames of length dims. Each data frame presents results for estimates from that dimension (i.e. x\$stimuli[[2]] presents results for dimension 2). Individuals that are discarded from analysis due to the minscale constraint are NA'd out. Each row contains data on a separate stimulus, and each data frame includes the following variables: c Estimate of the individual intercept. w1 Estimate of the individual slope. If viewing the results for a higher dimension, higher dimension results will appear as w2, w3, etc. R2 The percent variance explained for the respondent. This increases as more dimensions are estimated.
fits		A data frame of fit results, with elements listed as follows:
	SSE	Sum of squared errors.
	SSE.explained	Explained sum of squared error.
	percent	Percentage of total variance explained.
	SE	Standard error of the estimate, with formula provided in the article cited below.
	singular	Singular value for the dimension.
	Nrow	Number of rows/stimuli.
	Ncol	Number of columns used in estimation. This may differ from the data set due to columns discarded due to the minscale constraint.
	Ndata	Total number of data entries.
	Nmiss	Number of missing entries.
	SS_mean	Sum of squares grand mean.
	dims	Number of dimensions estimated.

---

plot.aldmck

*Aldrich-McKelvey Coordinate Distribution Plot*

---

## Description

plot.aldmck reads an aldmck object and plots the probability distribution of the respondents and stimuli.

## Usage

```
## S3 method for class 'aldmck'
plot(x, ...)
```

## Arguments

x                    an aldmck output object.  
 ...                  Other arguments to plot.

**Value**

A plot of the probability distribution of the respondent ideal points, along with the locations of the stimuli. If no self-placements were specified during estimation, no graphical plots will appear.

---

plot.aldmck\_negative    *Aldrich-McKelvey Negative Coordinate Distribution Plot*

---

### Description

plot.aldmck\_negative reads an aldmck object and plots the probability distribution of the respondents and stimuli with negative weights.

### Usage

```
## S3 method for class 'aldmck_negative'  
plot(x, xlim=c(-2,2), ...)
```

### Arguments

x	an aldmck output object.
xlim	vector of length 2, fed to the plot function as the xlim argument, which sets the minimum and maximum range of the x-axis.
...	other arguments to plot.

### Value

A plot of the probability distribution of the respondent ideal points, along with the locations of the stimuli. If no negative weights exist, either because respondent self-placements are not specified, or because all weights are positive, a plot indicating this in text is given.

---

predict.aldmck

*Predict method of aldmck objects*

---

**Description**

predict.aldmck reads an aldmck object and uses the estimates to generate a matrix of predicted values.

**Usage**

```
## S3 method for class 'aldmck'
predict(object, caliper=0.2, ...)
```

**Arguments**

object	A aldmck output object.
caliper	Caliper tolerance. Any individuals with estimated weights lower than this value are NA'd out for prediction. Since predictions are made by dividing observed values by estimating weights, very small weights will grossly inflate the magnitude of predicted values and lead to extreme predictions.
...	Ignored.

**Value**

A matrix of predicted values generated from the parameters estimated from a aldmck object.

**Author(s)**

Keith Poole <ktpoole@uga.edu>  
 Howard Rosenthal <hr31@nyu.edu>

---

predict.blackbt	<i>Predict method of blackbt objects</i>
-----------------	--

---

**Description**

predict.blackbt reads an blackbt object and uses the estimates to generate a matrix of predicted values.

**Usage**

```

## S3 method for class 'blackbt'
predict(object, dims=1, ...)

```

**Arguments**

object	A blackbox output object.
dims	Number of dimensions used in prediction. Must be equal to or less than number of dimensions used in estimation.
...	Ignored.

**Value**

A matrix of predicted values generated from the parameters estimated from a blackbt object.

---

stimuli	<i>Stimulus extraction function</i>
---------	-------------------------------------

---

**Description**

stimuli is a convenience function to extract the stimulus parameters from an aldmck, blackbox, or blackbt object.

**Usage**

```
stimuli(object)
```

**Arguments**

object            an aldmck, blackbox, or blackbt output object.

**Value**

The stimuli of the estimated output, which can also be recovered as `object$stimuli`. Please refer to the documentation of aldmck, blackbox, or blackbox\_transpose for specifics.

summary.aldmck

*Aldrich-McKelvey Summary*

---

**Description**

summary.aldmck reads an aldmck object and prints a summary.

**Usage**

```
## S3 method for class 'aldmck'
summary(object, ...)
```

**Arguments**

object            an aldmck output object.  
 ...              further arguments to print.

**Value**

A summary of an aldmck object. Reports number of stimuli, respondents scaled, number of respondents with positive and negative weights, R-squared, Reduction of normalized variance of perceptions, and stimuli locations.

summary.blackbox

*Blackbox Summary*

---

**Description**

summary.blackbox reads an blackbox object and prints a summary.

**Usage**

```
## S3 method for class 'blackbox'
summary(object, ...)
```

**Arguments**

```
object      a blackbox output object.
...         further arguments to print.
```

**Value**

A summary of a blackbox object. For each dimension, reports all stimuli with coordinates, individuals used for scaling, and fit. Also summarizes number of rows, columns, total data entries, number of missing entries, percent missing data, and sum of squares.

**Author(s)**

```
